(Received February 12, 2019; Accepted February 22, 2019)

#### Abstract

Taiwanofungus camphoratus is an edible and medicinal mushroom originating in Taiwan. Several researches have revealed T. camphoratus possessed various biological activities, including anti-cancer, immunomodulation, liver protection and anti-inflammation. Recently, it has been widely used in food supplements and drug development for its health benefits and medicinal properties. Therefore, the safety issue is the primary concern for consumers. The aim of this study was to evaluate the toxicological effects of T. camphoratus extract that was composed of extracts from cut-log cultivated fruiting body and solid-state culture of T. camphoratus. The genotoxicity tests, rodent and non-rodent repeated dose toxicity studies were performed. The results of the genetic toxicology tests including in vitro bacterial reverse mutation assay, in vitro chromosomal aberration test, and in vivo mouse bone marrow micronucleus assay were all negative that indicated neither mutagenicity nor clastogenicity was caused by T. camphoratus extract. Moreover, 13 -week and 26 -week repeated dose oral toxicity studies in rats showed that no significant adverse effects of T. camphoratus extract were found up to dosages of $3400 \mathrm{mg} / \mathrm{kg}$ and $1700 \mathrm{mg} / \mathrm{kg}$ for male and female rats, respectively. The results of 28 -day repeated dose oral toxicity study in beagle dogs showed no-observed-adverse-effect-level (NOAEL) of T. camphoratus extract up to dosage of $1500 \mathrm{mg} / \mathrm{kg}$ for male and female dogs. Accordingly, these results provided the safety information of $T$. camphoratus extract that supported for using in food supplements or medicinal usage.

Key words: T. camphoratus, Genotoxicity, Mutagenicity, Rat toxicity study, Beagle dog toxicity study

## INTRODUCTION

Taiwanofungus camphoratus, also known as "Niu-chang-chih", is a rare and precious medicinal fungus originating in Taiwan. Cinnamomum kanehirae Hayata (Lauraceae), a native tree of Taiwan, is the only natural host of T. camphoratus. T. camphoratus has been used as traditional medicine by the aboriginals in Taiwan to promote health, treat liver disease, drug and food intoxication, hangover, exhaustion and cancers (Geethangili and Tzeng, 2011; Wu, 1997). Many active components of $T$. camphoratus have been identified, such as polysaccha-
rides, terpenoids, benzenoids, nucleic acid, benzoquinone derivatives, steroids, and maleic/succinic acid derivatives (Geethangili and Tzeng, 2011; Lu et al., 2013). Triterpenoids are the most abundant compounds in fruiting body of T. camphoratus, but is much less in mycelium. Besides, several researches have revealed that T. camphoratus possessed a variety of pharmacological activities, including immune regulation (Chen et al., 2018; Lin et al., 2010; Lin et al., 2018), anti-cancer (Chang et al., 2013; Hseu et al., 2017; Shang et al., 2017), hepatoprotection (Chiu and Hua, 2016; Li et al., 2017; Wu et al., 2011), and anti-inflammation (Chen et al., 2017; Huang et al., 2014; Shie et
al., 2016).
The growth rate of wild T. camphoratus is very slow, therefore, different artificial cultivation methods have been developed to produce T. camphoratus to meet the increasingly market demand. It can be classified as cutlog culture, solid-state culture, submerged fermentation and dish culture. Culture medium and methods significantly affect the quality and quantity of components in $T$. camphoratus, thus pharmacological or toxicity effects of T. camphoratus products predominantly depends on cultivation techniques (Chung et al., 2016; Lu et al., 2013). Due to its multiple health benefits and medicinal properties, T. camphoratus has been wildly used in nutritional supplements, health food products and drug development. However, there is still no sufficient information regarding the toxicity properties of T. camphoratus. Currently, some toxicology studies have demonstrated the safety of T. camphoratus, but mostly focus on mycelium products. The 90 days repeated toxicity study showed the no-ob-served-adverse-effect-level (NOAEL) value of submerged fermentation and solid-state cultivation T. camphoratus mycelium is $3000 \mathrm{mg} / \mathrm{kg}$ and up to the dosage of $7.6 \mathrm{~g} / \mathrm{kg}$ in rats (Chen et al., 2010; Lo et al., 2016). The previous study also showed no adverse effects found in rats treated with mycelium of solid-state cultivation of T. camphoratus and no genotoxicity and mutagenic effects were observed (Lo et al., 2016; Lin et al., 2016).

This study aimed to investigate the toxicological effects of T. camphoratus extract that was composed of extracts from cut-log cultivated fruiting body and solid-state culture of T. camphoratus. Results from genotoxicity studies including bacterial reverse mutation test, mammalian chromosome aberration test and mammalian erythrocyte micronucleus test showed T. camphoratus extract did not induce genotoxic and mutagenic effects. Furthermore, the repeated dose oral toxicity tests in rats and beagle dogs demonstrated that no significant adverse effects of T. camphoratus extract were found up to dosage of $3400 \mathrm{mg} / \mathrm{kg}$ in male rats, $1700 \mathrm{mg} / \mathrm{kg}$ in female rats and $1500 \mathrm{mg} / \mathrm{kg}$ in both genders of beagle dogs. Taken together, these results support the safe use of T. camphoratus for human consumption.

## MATERIALS AND METHODS

All studies were performed at Level Biotechnology Inc. Preclinical Testing Center in compliance with the Good Laboratory Practice for Non-clinical Laboratory Studies (FDA, 21 CFR, Part 58), Good Laboratory Practice for Non-clinical Laboratory Studies (Ministry of Health and Welfare, R.O.C., 3rd ed., 2006) and OECD Principles
of Good Laboratory Practice (as revised in 1997). These studies were also conducted in accordance with ICH (2009) M3 (R2) Non-Clinical Safety Studies for the Conduct of Human Clinical Trials and Marketing Authorization for Pharmaceuticals (CPMP/ICH/286/95).

## Test substance

The test article, T. camphoratus extract (named as LEAC-102), was composed of ethanol and water extracts from cut-log cultivated fruiting body (FB) and solid-state culture (SC) of T. camphoratus that provided by Taiwan Leader Biotech Corp. (Taipei, Taiwan). The cut-log cultivated FB and solid-state culture of T. camphoratus were manufactured by R\&D Center of Taiwan Leader Biotech Corp. (Taichung, Taiwan). The dry powders of FB and SC were mixed in the ratio of $1: 10(\mathrm{w} / \mathrm{w})$ and were extracted with 10 volumes of $95 \%$ ethanol for 2 hr twice, followed by extraction with 10 volumes of boiled water for 2 hr twice. The ethanol and water extracts from FB and SC were combined and concentrated to obtain LEAC-102. 1 gram of T. camphoratus extract equivalent to the extract from dried raw material of 0.22 g of fruit body and 2.2 g of solid-state culture.

## Bacterial reverse mutation test

The histidine-dependent Salmonella typhimurium strains TA98, TA100, TA102, TA1535 and TA1537 (Moltox Inc., Boone, NC) were used to evaluate the genotoxicity of $T$. camphoratus extract. T. camphoratus extract was dissolved in DMSO to obtain the dosing solution and the highest dose of this study was set at $5 \mathrm{mg} /$ plate based on the results of dose range finding test in TA100. Hence, five concentrations, $0.050,0.158,0.50,1.58,5 \mathrm{mg} /$ plate, were used in this study. Positive controls, negative control (sterile water), vehicle control (dimethylfloxide, DMSO) and test solutions with or without metabolic activation (S9 mixture, Aroclor 1254-induced; Moltox, BOONE, NC ) were included in study. Positive controls are as follows (all reagents were from Sigma Aldrich, St. Louis, MO), (1) without S9: 2-nitrofluorene for TA98, sodium azide for TA100 and TA1535, mitomycin C for TA102, and 9-aminoacridine for TA1537, (2) with S9: 2-aminoanthracene for TA98, TA102, TA1535 and TA1537, benzo[a]pyrene for TA100. 0.05 mL of test solutions, 0.1 mL of bacterial broth and 0.5 mL phosphate buffer ( $0.2 \mathrm{M}, \mathrm{pH} 7.4$ ) (without S 9 metabolic activation) or 0.5 mL S 9 mixture were mixed with the molten top agar and poured onto the surface of a minimal glucose agar plate. The plates were incubated at $37^{\circ} \mathrm{C}$ for $48-72 \mathrm{hr}$ then the number of revertant colonies per plate was counted. The data of revertant colonies count on triplicate plates
was represented with Mean $\pm$ S.D., and its coefficient of variation (CV.) was calculated as well. If an increase in revertants of $T$. camphoratus extract treated plates (more than 2 -fold in TA98, TA100 and TA102 or 3-fold in TA1535 and TA1537) were noted, statistical analysis by ANOVA and Dunnett's test would be performed. Besides, an additional dose-related response analysis will be used if the ANOVA results are statistically significant. Probability of $0.05(p<0.05)$ was used as the criterion of significance.

## In vitro Mammalian Chromosome Aberration Test

Chinese Hamster Ovary (CHO-K1) cell line was obtained from Bioresource Collection and Research Center (BCRC, Hsinchu, Taiwan). CHO-K1 cell was cultured in HAM's F12 medium with 2 mM of L-glutamine, $100 \mathrm{U} / \mathrm{mL}$ of penicillin and streptomycin, $10 \%$ of heatinactivated FBS (all supplements were from Biological industries, Grand Island, NY) in a humidified atmosphere containing $5 \% \mathrm{CO}_{2}$ at $37^{\circ} \mathrm{C}$. T. camphoratus extract was dissolved in DMSO to obtain the test solution of 6.2, 18.5, $55.6,166.7,500$ and $1500 \mu \mathrm{~g} / \mathrm{mL}$ that used in dose range finding cytotoxicity test for selecting the high dose used in main study. CHO-K1 cells ( $3-5 \times 10^{5}$ cells/dish) were seeded in 6 cm culture dishes and culture for 24 hr before treatment. For short-term treatment with or without S9 activation, cells were treated with $T$. camphoratus extract (18.5, $55.6,166.7 \mu \mathrm{~g} / \mathrm{mL}$ ), $0.5 \mu \mathrm{~g} / \mathrm{mL}$ mitomycin C (positive control for without S9) or $25 \mu \mathrm{~g} / \mathrm{mL}$ benzo(a)pyrene (positive control for with S9) for 3-6 hr. For long-term treatment without S 9 activation, cells were treated with $T$. camphoratus extract ( $6.2,18.5,55.6 \mu \mathrm{~g} / \mathrm{mL}), 0.5 \mu \mathrm{~g} / \mathrm{mL}$ mitomycin C (positive control) for 18-22 hr. The 1\% DMSO solution and culture medium were used as vehicle control and negative control, respectively. After treatment, $0.1 \mu \mathrm{~g} / \mathrm{mL}$ Colcemid solution was added into culture medium for 1-3 hr. Cells were harvested and treated with hypotonic solution ( 0.075 M KCl ) and fixed with a mixture of methanol/acetic acid (3:1, v/v). Cells were placed on clean slides and stained with Giemsa solution. The chromosome aberration was evaluated by examination of at least 300 well-spread metaphase cells with a number of centromeres equal to the modal number $(20 \pm 2)$ for each dose in duplicate. The structural chromosome aberrations, including chromatid breakage (ctb) and exchange (cte), chromosome breakage (csb) and exchange (cse), and other abnormalities, such as polyploidy, shall be scored and recorded by photographing. The statistical evaluation was analyzed by Poisson distribution. The statistical significance level was defined at $p<0.05$. The number of cells
with chromosome aberration in positive control should be significantly increased comparing with that in negative control. If more than two testing dosages show significant increase in number of cells with chromosome aberration, it was considered that the test article would induce structural chromosome aberration in $\mathrm{CHO}-\mathrm{K} 1$ cells. If only one testing dosage shows significant increase in number of cells with chromosome aberration, the Cochran-Armitage trend test (C-A test) will be performed for dose-dependent analysis. Only if there is a dose dependent trend in number of cells with chromosome aberration, the test article would be considered genotoxic in CHO-K1 cells.

## Mammalian erythrocyte micronucleus test

The micronucleus test was performed using 7-8 weeks old ICR mice (BioLASCO Taiwan Co. Ltd) and the test article, T. camphoratus extract, was prepared in sterile water at the designated concentration. Animals were housed in the SPF grade animal room in the AAALAC International accredited facility of Level Biotech. Inc. under 12 hr light $/ 12 \mathrm{hr}$ dark cycle at $19-23^{\circ} \mathrm{C}$ with relative humidity $35-75 \%$. The highest dosage was determined based on the result of preliminary dose range finding. The mice were randomly divided into 5 groups, including negative control, positive control and three treatment groups, 10 mice in each group of 5 male and 5 female. Mice were orally administered T. camphoratus extract at doses of 1700,3400 and $6800 \mathrm{mg} / \mathrm{kg}$ bw. The positive control group was intraperitoneally injected with $80 \mathrm{mg} / \mathrm{kg}$ bw cyclophosphamide and negative control group was given sterile water orally. The daily dosing volume for oral dosing was $20 \mathrm{~mL} / \mathrm{kg}$ bw and BID dosing was conducted at 2-3 hr interval ( $10 \mathrm{~mL} / \mathrm{kg}$ bw per dosing time). The mortality of animals was observed once daily during study period and peripheral blood samples were collected from tail vein at $48 \pm 2$ and $72 \pm 2 \mathrm{hr}$ after dosing. The positive control group was sampled only at $48 \pm 2 \mathrm{hr}$ after dosing. The peripheral blood was smeared on the acridine orange coated slide, and the staining was performed in room temperature for 2-3 hr. The fluorescent microscopes (Zeiss AXIO Scope.A1 and Zeiss AXIO Imager.A1) with 460-490 nm exciting and 515 nm long pass filter were used for polychromatic erythrocytes (PCE) and micronucleus identification and counting. The proportion of PCE in erythrocytes was determined by counting at least 2000 erythrocytes. At least 4000 PCE per animal were scored for frequency of micronucleated cells (MN \% $\%$ PCE). The data was presented with mean $\pm$ S.D. The micronucleus frequency was analyzed by Poisson distribution. Probability of $0.05(p<0.05)$ was used as the criterion of significance. If significant difference has shown in testing

## J.-Y. Lin et al.

group comparing with concurrent negative control, the Cochran-Armitage trend test (C-A test) will be used for dose dependent analysis. Furthermore, the test article will be considered to display genotoxic if the dose dependent response has existed. In addition, if the PCE percentage of testing group was $50 \%$ less than the negative control, it indicated that the test article inhibit erythropoiesis. The study was approved by the Institutional Animal Care and Use Committee (IACUC number 160101-C1).

## 13-week repeated dose oral toxicity test in rats with a 4-week recovery

The 6 weeks old Sprague Dawley (SD) rats (BioLASCO Taiwan Co. Ltd.) were randomly divided into four groups, 12 rats per sex in each group with additional recovery groups ( 6 animals/sex/vehicle control and high dose group). The animals were housed in the AAALAC International accredited facility of Level Biotech. Inc. under 12 hr light/ 12 hr dark cycle and the temperature of animal room was at $19-23^{\circ} \mathrm{C}$ with relative humidity $35-75 \%$. The rats received T. camphoratus extract orally at doses of 425,850 and $1700 \mathrm{mg} / \mathrm{kg}$ once daily for 13 weeks and the recovery animals in vehicle control and high dose groups were allowed a 4 weeks treatment free period. The animals had free access to diet and the clinical signs were observed during the experiment period. The body weight and food consumption were measured weekly. Hematology, serum biochemistry, urinalysis and gross necropsy were conducted on all surviving animals at scheduled sacrifice. Organs and tissues were collected, weighed and examined microscopically. The data was presented with mean $\pm$ S.D. and analyzed by oneway ANOVA followed by Dunnett's method (SPSS, Ver. 12.0 or Ver. 22.0). In addition, student's $t$-test was used to analyze the data of recovery groups. The statistical significance level was defined at $p<0.05$. The study was approved by the Institutional Animal Care and Use Committee (IACUC number 151101).

## 26-week repeated dose oral toxicity test in rats with a 4-week recovery

The 6 weeks old Sprague Dawley (SD) rats (BioLASCO Taiwan Co. Ltd) were randomly divided into four groups, 22 rats per sex in each group with additional recovery groups ( 12 animals/sex/vehicle control and high dose group). The animals were housed in the AAALAC International accredited facility of Level Biotech. Inc. under 12 hr light $/ 12 \mathrm{hr}$ dark cycle and the temperature of animal room was at $19-23^{\circ} \mathrm{C}$ with relative humidity $35-75 \%$. The male rats received $T$. camphoratus extract orally at doses of 850,1700 and $3400 \mathrm{mg} / \mathrm{kg}$ and
female rats received 425,850 and $1700 \mathrm{mg} / \mathrm{kg}$ once daily for 26 weeks and the recovery animals in vehicle control and high dose groups were allowed a 4 weeks treatment free period. The animals had free access to diet and the clinical sings were observed during the experiment period. The body weight and food consumption were measured weekly. Hematology, serum biochemistry, urinalysis were conducted on all surviving animals on week 13 and at the end of the study. Organs and tissues were collected, weighed and examined microscopically. The data was presented with mean $\pm$ S.D. and analyzed by oneway ANOVA followed by Dunnett's method (SPSS, Ver. 12.0 or Ver. 22.0). In addition, student's $t$-test was used to analyze the data of recovery groups. The statistical significance level was defined at $p<0.05$. The study was approved by the Institutional Animal Care and Use Committee (IACUC number 160202 and 160202-C1).

## 28-day repeated dose oral toxicity test with a 14-Day recovery in beagle dogs

The 6-7 months old male and female beagle dogs were purchased from Covance Inc. (Cumberland, VA). The animals were housed individually by using stainless cage in the AAALAC International accredited facility of Level Biotech. Inc. under 12 hr light $/ 12 \mathrm{hr}$ dark cycle and the temperature of animal room was at $19.2-22.3^{\circ} \mathrm{C}$ with relative humidity $43.7-67.4 \%$. The $\operatorname{diet}(400 \mathrm{~g} /$ animal/day) was applied once daily for approximately 1 week and twice daily ( $200 \mathrm{~g} /$ animals/time) thereafter. Naïve beagle dogs were randomly assigned to four groups (vehicle control, 540,900 and $1500 \mathrm{mg} / \mathrm{kg} /$ day groups, 3 animals $/ \mathrm{sex} /$ group) with additional recovery groups ( 2 animals/sex/ vehicle control and $1500 \mathrm{mg} / \mathrm{kg} /$ day groups). The animals were orally administered with T. camphoratus extract in gelatin capsules (Empty Porcine Hard Gelatin Capsules, Torpac Inc., Fairfield, NJ) or empty capsules (vehicle control) three times daily that a quantity of one-third total daily dose was given at 2 hr interval for consecutive 28 days with designated doses. At the end of treatment period, the recovery animals of vehicle control and high dose groups were maintained for a 14 days treatment free period. The mortality, body weight, food consumption and clinical signs were observed during the study period. Electrocardiographic (ECG) examination was performed on animals during pre-dose period, Day 28 (end of treatment) and Day 42 (end of recovery). Ophthalmologic examinations were performed for all animals at the grouping day and before terminal sacrifice. Hematology, serum chemistry and urinalysis were performed for all animals at pre-dose and at the end of treatment and recovery periods. Gross necropsy and histopathology exami-

## Toxicity studies of T. camphoratus extract

nation are performed at the end of study. The study was approved by the Institutional Animal Care and Use Committee (IACUC number 171104-C1 and 171104-C2).

## RESULTS AND DISCUSSION

## Bacterial reverse mutation test

The genotypes of five Salmonella typhimurium strains (TA98, TA100, TA102, TA1535, and TA1537) for this study were identified and met the criteria as described in Table S1-S2. The results of dose range finding test in TA100 showed T. camphoratus extract had no cytotoxic and mutagenic effect (Table S3), therefore, 5 doses ( $0.050,0.158,0.50,1.58$ and $5 \mathrm{mg} /$ plate) of $T$. camphoratus extract were chosen in this test. The test results were summarized in Table 1. The revertant colonies in positive control group were over two-fold (in TA98, TA100, and TA102) and three-fold (in TA1535 and TA1537) compared to negative control groups.
T. camphoratus extract at all testing doses (0.050$5 \mathrm{mg} /$ plate) did not cause significant increase in revertant colony number under both with and without S9 metabolic activation conditions. Thus it's indicated that no mutagenic effect of T. camphoratus extract was noted on five S. typhimurium strains in all testing groups.

## Mammalian Chromosome Aberration Test

Three analyzable concentrations used in the chromosome aberration test were selected by cytotoxicity test that produced greater than $50 \%$ cell viability. The cell viability of testing concentrations at $18.5,55.6,166.7 \mu \mathrm{~g} / \mathrm{mL}$ for 3 hr treatment without S9 metabolic activation were $80.26 \pm 8.72 \%, 88.19 \pm 11.98 \%$ and $89.71 \pm 10.08 \%$, respectively. Of 3 hr treatment in the presence of S 9 , the cell viability of testing concentrations at $18.5,55.6,166.7$ $\mu \mathrm{g} / \mathrm{mL}$ were $92.55 \pm 7.03 \%, 91.95 \pm 10.94 \%$ and $97.32 \pm$ $9.02 \%$, respectively. In long term ( 18 hr ) treatment without S9, the cell viability of testing concentrations at 6.2 , $18.5,55.6 \mu \mathrm{~g} / \mathrm{mL}$ were $146.82 \pm 8.95 \%, 110.18 \pm 17.80 \%$ and $51.64 \pm 7.41 \%$, respectively (Table S4). The result of chromosome aberration was summarized in Table 3. Clear positive responses in positive control group were observed that the cell numbers of chromosome aberration were 22,35 and 50 in short term with or without S9 and long term without S9, respectively. The chromosome aberrations in T. camphoratus extract treated cells were 1,1 and 0 at $166.7,55.6$ and $18.5 \mu \mathrm{~g} / \mathrm{mL}$, respectively under 3 hr without S9 and 1, 0 and 3 at 166.7, 55.6 and $18.5 \mu \mathrm{~g} / \mathrm{mL}$, respectively under 3 hr with S9. Moreover, the chromosome aberrations were 2,2 and 2 at 55.6, 18.5 and $6.2 \mu \mathrm{~g} / \mathrm{mL}$, respectively under 18 hr without S 9 . The
results showed that no significant increase in chromosome aberrations at all tested dosages under the test conditions and indicated that $T$. camphoratus extract could be considered nonmutagenic in this system.

## Mammalian erythrocyte micronucleus test

According to the dose range finding test in ICR mice, animals were found no abnormal symptoms and mortality at the highest dose ( $6800 \mathrm{mg} / \mathrm{kg}$ ). Therefore, the doses of $T$. camphoratus extract were set as $80,1700,3400$ and $6800 \mathrm{mg} / \mathrm{kg}$ bw in micronucleus test. As shown in Table 2, the PCE percentage of negative control group at 48 and 72 hr were $3.28 \pm 0.04 \%$ and $3.34 \pm 0.05 \%$ in male, $3.44 \pm 0.11 \%$ and $3.46 \pm 0.11 \%$ in female, respectively. The PCE percentage of positive control group at 48 hr was $1.02 \pm 0.04 \%$ in male and $1.40 \pm 0.38 \%$ in female. As expected, the inhibition of erythropoiesis by cyclophosphamide was noted based on the decreased PCE percentage, while no significant decrease in PCE percentage was observed in all testing groups which is indicated that $T$. camphoratus extract did not inhibit erythropoiesis. The micronucleus frequency of 1700,3400 and $6800 \mathrm{mg} / \mathrm{kg}$ T. camphoratus extract at 48 hr after dosing in male was $0.72 \pm 0.41 \%$ PCE, $0.42 \pm 0.11 \%$ PCE and $0.44 \pm 0.22 \% \mathrm{PCE}$ and that at 72 hr after dosing in male was $0.66 \pm 0.23 \%$ PCE, $0.50 \pm 0.27 \%$ PCE and 0.34 $\pm 0.09 \%$ PCE respectively. The micronucleus frequency of 1700,3400 and $6800 \mathrm{mg} / \mathrm{kg}$ T. camphoratus extract at 48 hr after dosing in female was $0.42 \pm 0.29 \%$ PCE, 0.48 $\pm 0.20 \%{ }_{o} \mathrm{PCE}$ and $0.56 \pm 0.26 \% \mathrm{PCE}$ and that at 72 hr after dosing in female was $0.48 \pm 0.30 \%$ PCE, $0.52 \pm$ $0.18 \%$ PCE and $0.48 \pm 0.34 \%$ PCE respectively. There was no significant difference in the micronucleus frequency between negative control and all testing groups of $T$. camphoratus extract in both genders under Poison distribution analysis. Accordingly, T. camphoratus extract was considered negative in inducing micronucleus formation. The micronucleus frequency of positive control was more than double of that in negative controls, thereby confirming this study was authentic and valid. In conclusion, $T$. camphoratus extract was non-genotoxic and would not affect erythropoiesis in mice under the test condition.

## 13-week repeated dose oral toxicity study with a 4-week recovery in rats

In the study, 13-week daily oral administered of $T$. camphoratus extract in rats, there was no test article-related death or ophthalmologic abnormality (Table S5) and no significant changes in body weight (Fig. 1) and food consumption were observed. Only female rats in $1700 \mathrm{mg} / \mathrm{kg}$ recovery group had a higher mean body

All data presented as mean $\pm$ S.D. ${ }^{*} p<0.05$ compared to vehicle control.
${ }^{2}$ The statistical evaluation was analyzed by Poisson distribution in comparison with historical data of negative control because the aberration frequency of concurrent vehicle control is zero. ${ }^{3}$ The statistical evaluation was analyzed by Poisson distribution in comparison with concurrent vehicle control.

Fig. 1. Effects of repeated oral dose ( 13 weeks) of T. camphoratus extract on body weight in rats. Results of body weight in (A) male rats and (B) female rats treated with T. camphoratus extract for 13 weeks with additional 4 recovery weeks. No significant changes in body weight were observed in T. camphoratus extract treated animals. All data presented as mean $\pm$ S.D.
weight gains in week 3 and a lower mean body weight gains in week 14 (Table S6), and male rats in high-dose main study group had lower average food consumption in week 1 when compared to vehicle control (Table S7). However, the values were within the range of historical
control data and the changes were infrequent and sporadic, thus it was considered as non-treatment related. One female rat from $425 \mathrm{mg} / \mathrm{kg}$ group showed corneal opacity in left eye before necropsy that it was considered incidental and unrelated to treatment due to lack of dose respons-

Toxicity studies of T. camphoratus extract
es and/or microscopic correlations. Additionally, no treatment related clinical signs were observed on all animals although, several signs including hair loss, wounds and teeth damage were still observed in few animals due to housing-related behavior (Table S8). One female rat in $850 \mathrm{mg} / \mathrm{kg}$ group developed dyspnea, audible respiration and soft feces from study day 78 through the study termination, following macropiscally and microscopically evaluation, the spontaneous lesion in large intestine, megacolon, was observed. Therefore, the data (body weight, food consumption, clinical pathology parameters and organ weights) from this female rat was not included in statistic evaluation.

In clinical pathology evaluation, no significant toxicity evidences were found among all treatment groups. Some statistical differences were noted when compared to vehicle control. However, all values were within normal physiological ranges. The results of hematology and serum biochemistry parameters were summarized in Table 4-5. The female rats in $1700 \mathrm{mg} / \mathrm{kg}$ recovery group showed lower mean corpuscular volume (MCV) and mean corpuscular hemoglobin ( MCH ) compared to vehicle control recovery group. The male rats in $850 \mathrm{mg} / \mathrm{kg}$ group showed higher phosphorus (P) and the female rats in $1700 \mathrm{mg} / \mathrm{kg}$ main study group showed higher glucose and cholesterol compared to vehicle control. The male rats in $1700 \mathrm{mg} / \mathrm{kg}$ recovery group showed lower albumin and higher chloride $(\mathrm{Cl})$ and female rats in $1700 \mathrm{mg} / \mathrm{kg}$ recovery group showed lower sodium $(\mathrm{Na})$ and chloride $(\mathrm{Cl})$ compared to vehicle control (Table 5). Moreover, there were no $T$. camphoratus extract-related changes in urinalysis after 13 weeks of administration (data not shown). As shown in table 6 , the heart weight of male rats at $425 \mathrm{mg} / \mathrm{kg}$ group and pituitary weight of male rats at $1700 \mathrm{mg} / \mathrm{kg}$ recovery group were statistical lower than respective control groups. In females, statistical higher liver weight was noted in $1700 \mathrm{mg} / \mathrm{kg}$ main study group and higher adrenal weights were noted in all three treatment groups (425, 850 and $1700 \mathrm{mg} / \mathrm{kg}$ ) compared to vehicle control, but all values were within the historical control data. Additionally, no significant difference was noted between control and $1700 \mathrm{mg} / \mathrm{kg}$ recovery groups in the organ weight data of female recovery group, and the significant differences in organ weight data described above, including adrenal and liver, were not seen. All organ weight changes noted above were considered incidental and unrelated to T. camphoratus extract treatment, due to lack of dose responses and/or microscopic correlations. Macroscopically, no treatment related abnormality was found in all animals. A spontaneous thymic atrophy was noted only in one female rat in vehicle control recovery group. Further-
more, there were no T. camphoratus extract-related histopathological lesions in all animals at $1700 \mathrm{mg} / \mathrm{kg}$ group (Table S9). Base on the results, the NOAEL of T. camphoratus extract in this study is $1700 \mathrm{mg} / \mathrm{kg}$.

## 26-week repeated dose oral toxicity study with a 4-week recovery in rats

T. camphoratus extract were administered in rat orally, daily for 26 weeks and the results showed no mortality, no ophthalmologic abnormality and no significant differences in mean body weight. T. camphoratus extract were daily oral administered in rats for 26 weeks and the results showed no mortality, no ophthalmologic abnormality and no significant differences in mean body weights (Fig. 2). In body weight gain evaluation, some statistical differences were observed (Table S10-11), but all values were within the range of historical control data. Only the body weight gain of male rats in $3400 \mathrm{mg} / \mathrm{kg}$ recovery group was out of the lower limit of historical control range, however, this finding was not correlated to body weight and food consumption. Thus, the body weight changes were considered incidental and unrelated to treatment. There were no T. camphoratus extract related effects on food consumption, but some statistical changes were also noted in male rats (Table S12). Some clinical signs such as hail loss, wounds, teeth damage and swelling were observed during the study period and the results were summarized in Table S13. These findings might be caused by housing behavior or individual variation and were considered unrelated to T. camphoratus extract.

There was no toxicity evidences were noted for hematology, serum chemistry and urinalysis parameters among the vehicle control group and T. camphoratus extract treatment groups, whereas some statistical difference were observed in both male and female rats. The interim analysis results of hematology analysis in male rats showed higher neutrophil in $3400 \mathrm{mg} / \mathrm{kg}$ main group and lower red blood cell (RBC) in $3400 \mathrm{mg} / \mathrm{kg}$ recovery group when compared to vehicle control. In female rats, white blood cell (WBC) in $1700 \mathrm{mg} / \mathrm{kg}$ main group was lower than vehicle control and WBC, RBC, hemoglobin $(\mathrm{Hb})$ and hematocrit (Hct) in $1700 \mathrm{mg} / \mathrm{kg}$ recovery group was lower than vehicle control recovery group. In terminal analysis, there was no statistical difference in all T. camphoratus extract treated male rats when compared to vehicle control /vehicle control recovery groups. In female rats, there was no statistical difference among vehicle control and all test article treatment groups in the data of main study groups. Lower RBC, $\mathrm{Hb}, \mathrm{Hct}$ and platelet were noted in $1700 \mathrm{mg} / \mathrm{kg}$ recovery group when compared to vehicle control recovery group (Table 7).

${ }^{6}$ Prostates and seminal: Prostates and seminal vesicles with coagulating glands
Historical control data for male rats: Heart (g): 1.256-1.930; Pituitary (g): 0.00938-0.01631
Historical control data for female rats: Adrenals (g): 0.04933-0.08974; Liver (g): 6.137-9.955

Fig. 2. Effects of repeated oral dose ( 26 weeks) of T. camphoratus extract on body weight in rats. Results of body weight in (A) male rats and (B) female rats treated with T. camphoratus extract for 26 weeks with additional 4 recovery weeks. No significant changes in body weight were observed in T. camphoratus extract treated animals. All data presented as mean $\pm$ S.D.

In interim analysis of serum biochemistry analysis, the results of male rats in main study groups showed higher values in glucose ( $3400 \mathrm{mg} / \mathrm{kg}$ ), albumin (in 1700 and $3400 \mathrm{mg} / \mathrm{kg}$ ), alkaline phosphatase (ALP) ( $3400 \mathrm{mg} / \mathrm{kg}$ ), cholesterol ( $3400 \mathrm{mg} / \mathrm{kg}$ ), calcium ( 850,1700 and 3400 $\mathrm{mg} / \mathrm{kg}$ ), phosphorus ( $3400 \mathrm{mg} / \mathrm{kg}$ ), amylase ( 3400 mg / kg ), sodium ( 1700 and $3400 \mathrm{mg} / \mathrm{kg}$ ), potassium ( 1700 and $3400 \mathrm{mg} / \mathrm{kg}$ ) and chloride ( 850,1700 and $3400 \mathrm{mg} /$ kg ) as compared to vehicle control. In male recovery rats, statistical higher glucose, albumin, ALP, amylase, sodium
and chloride and lower potassium were noted in $3400 \mathrm{mg} /$ kg recovery group when compared to vehicle recovery group. In female main study groups, lower aspartate aminotransferase (AST) $(425,850$ and $1700 \mathrm{mg} / \mathrm{kg})$, higher glucose ( $1700 \mathrm{mg} / \mathrm{kg}$ ), lower blood urea nitrogen (BUN) $(1700 \mathrm{mg} / \mathrm{kg})$, lower creatinine ( $850 \mathrm{mg} / \mathrm{kg}$ ), higher cholesterol ( 850 and $1700 \mathrm{mg} / \mathrm{kg}$ ) and lower sodium ( 425 and $850 \mathrm{mg} / \mathrm{kg}$ ) were noted. In female recovery rats, higher total protein, albumin, cholesterol, calcium and amylase were noted in $1700 \mathrm{mg} / \mathrm{kg}$ recovery group. In terminal

All data presented as mean $\pm$ SD. ${ }^{*} p<0.05$ compared to vehicle control. an $=11 ; \mathrm{b} \mathrm{n}=9 ;{ }^{\mathrm{c}} \mathrm{n}=10$
Historical control data for male rats (interim analysis): Glucose (mg/dL): 55.51-191.63; Albumin (g/dL): 4.29-5.41; ALP (U/L): 147.56-457.63;Cholesterol (mg/dL): 33.84-99.54; Ca²+ $(\mathrm{mg} / \mathrm{dL}): 9.20-10.71 ; \mathrm{P}(\mathrm{mg} / \mathrm{dL}): 5.26-8.87$; Amylase (U/L): $991.8-2284.8 ; \mathrm{Na}(\mathrm{mmol} / \mathrm{L}): 142.63-155.12 ; \mathrm{K}(\mathrm{mmol} / \mathrm{L}): 4.637-6.704 ; \mathrm{Cl}(\mathrm{mmol} / \mathrm{L}): 80.21-111.09$ Historical control data for male rats (terminal analysis): Albumin (g/dL): 3.53-4.43; ALP (U/L): 108.05-302.17; K (mmol/L): 3.989-5.337; Glucose (mg/dL): 55.51-191.63; Amylase (U/L): $991.8-2284.8 ; \mathrm{Na}(\mathrm{mmol} / \mathrm{L}): 142.63-155.12 ; \mathrm{K}(\mathrm{mmol} / \mathrm{L}): 4.637-6.704 ; \mathrm{Cl}(\mathrm{mmol} / \mathrm{L}): 80.21-111.09$
Historical control data for female rats (interim analysis): AST (U/L): 94.02-243.16; Glucose ( $\mathrm{mg} / \mathrm{dL}$ ): 67.97-170.64; BUN ( $\mathrm{mg} / \mathrm{dL}$ ): 11.66-24.38; Creatinine ( $\mathrm{mg} / \mathrm{dL}$ ): 0.0-0.8; Cholesterol $(\mathrm{mg} / \mathrm{dL}): 34.84-113.40 ; \mathrm{Na}(\mathrm{mmol} / \mathrm{L}): 143.36-156.87$; Total protein (g/dL): 6.49-8.69; Albumin (g/dL): 4.84-6.78; Ca²+ (mg/dL): 9.71-11.66; Amylase (U/L): 664.0-1574.6; Historical control
$\mathrm{Ca}^{2+}(\mathrm{mg} / \mathrm{dL}): 9.64-10.93 ;$ Cholesterol ( $\mathrm{mg} / \mathrm{dL}$ ): 30.13-110.13; Amylase (U/L): 666.8-1482.9; Cl (mmol/L): 89.07-111.57
analysis, the main study male rats showed higher albu$\min (1700$ and $3400 \mathrm{mg} / \mathrm{kg}$ ), ALP ( 1700 and $3400 \mathrm{mg} / \mathrm{kg}$ ) and potassium ( $3400 \mathrm{mg} / \mathrm{kg}$ ) compared to vehicle control. There was no statistical difference between vehicle control recovery group and $3400 \mathrm{mg} / \mathrm{kg}$ recovery group of males. In main study female rats, the results showed higher cholesterol ( 850 and $1700 \mathrm{mg} / \mathrm{kg}$ ), amylase ( $1700 \mathrm{mg} /$ kg ) and chloride ( $1700 \mathrm{mg} / \mathrm{kg}$ ) compared to vehicle control. In female recovery rats, lower AST, higher glucose and calcium in $1700 \mathrm{mg} / \mathrm{kg}$ recovery group were noted (Table 8). To summarize, the values described above were all within normal physiological range except albumin (interim analysis results from male recovery group). According to the magnitude of change in serum albumin value, this difference was not considered to be of toxicological significance. In addition, the urine analysis results showed no T. camphoratus extract related effects were observed (data not shown).

The absolute and relative organ weight results of both genders showed no significant difference between T. camphoratus extract treated groups and vehicle control, except adrenal (Male: 850 and $3400 \mathrm{mg} / \mathrm{kg}$; Female: 850 and $1700 \mathrm{mg} / \mathrm{kg}$ ), liver (Male: 850, 1700 and $3400 \mathrm{mg} / \mathrm{kg}$; Female: 850 and $1700 \mathrm{mg} / \mathrm{kg}$ ), heart (Male: $3400 \mathrm{mg} / \mathrm{kg}$ ) and pituitary (Female: $1700 \mathrm{mg} / \mathrm{kg}$ ) (Table $9-10$ ). The values of mean liver weight and mean liver / body weight ratio of high dose ( $3400 \mathrm{mg} / \mathrm{kg}$ ) males were out of the upper limits of historical control range. Following histopathological examination of the liver samples, no test article related lesions were observed. In addition, the significant differences in absolute and relative organ weight data described above, including adrenal and liver, were not seen in the data of male recovery group. Though the values of mean adrenal weight and mean adrenal / body weight ratio of $1700 \mathrm{mg} / \mathrm{kg}$ females were out of the upper limits of historical control range, the histopathological findings in adrenal of $1700 \mathrm{mg} / \mathrm{kg}$ females were not significantly different from vehicle control females. Besides, there was no significant difference in relative adrenal weight data between vehicle control recovery group and $1700 \mathrm{mg} / \mathrm{kg}$ recovery group. Moreover, the significant differences in female liver weight data described above were not seen in high-dose recovery animals. All organ weight changes noted above were not considered to be of toxicological significance, due to lack of statistically significant evidence from microscopic evaluation. The gross necropsy findings showed spontaneous abnormalities found in two male vehicle control rats with atrophy in testes and epididymis and in one female rat ( $425 \mathrm{mg} / \mathrm{kg}$ group) with a focal mass ( $<1 \mathrm{~cm}$ in diameter) in thorax. Following histopathological examination,
minimal to moderate diffuse atrophy were noted in testes and epididymis of male rats and adenocarcinoma in focal mammary glands of female rat was observed. Of the histopathological examination in all animals in high-dose group, no T. camphoratus extract related histopathological lesions were observed (Table S14). The NOAEL in this study is $3400 \mathrm{mg} / \mathrm{kg} /$ day for male rats, and $1700 \mathrm{mg} /$ $\mathrm{kg} /$ day for female rats.

## 28-days repeated dose oral toxicity study with a 14-Day recovery in beagle dogs

The beagle dogs received capsules containing T. camphoratus extract for consecutively 28 days and the results showed no T. camphoratus extract related mortality, ophthalmologic abnormality, clinical signs of toxicity and no significant differences on body weight (Fig. 3) and food consumption evaluation. In daily observation of clinical signs, several signs were noted and described as follow. As we know, dogs have a natural tendency to vomit. In this study, vomiting was observed mostly during the first week (adaptation period or affected due to over eating). Vomiting was mostly observed during the week 1-week 2 with one feeding of diet per day and the frequency of vomiting was reduced afterwards (twice daily feeding after week 2). In addition, un-dissolved capsule was vomited by one male dog of the $540 \mathrm{mg} / \mathrm{kg}$ group (Day 20) and one female dog of the $1500 \mathrm{mg} / \mathrm{kg}$ group (Day 9). The vomited capsules were re-administered to animal within 6 hr of the total times for dosing. Additionally, the vomi-tus-containing test article-like substance was noted in one female of the $900 \mathrm{mg} / \mathrm{kg}$ group and in three females of the $1500 \mathrm{mg} / \mathrm{kg}$ group. These findings were not considered to be of toxicological significance since they were sporadic and occurring with a mild severity in observed animals.

Some animals were also showed watery stool (male: all groups; female: control and $1500 \mathrm{mg} / \mathrm{kg}$ ), soft stool (male: control and $900 \mathrm{mg} / \mathrm{kg}$; female: $900 \mathrm{mg} / \mathrm{kg}$ ) and poor appetite (male: all groups; female: control and $900 \mathrm{mg} / \mathrm{kg}$ ). The gastrointestinal disturbances observed (soft stools and/or watery stool) were considered unrelated to the treatment since they were sporadic, not dose related and no pathologic findings were observed from microscopic evaluation. No correlated effects were noted between poor appetite and body weights.

Furthermore, one male dog of the $425 \mathrm{mg} / \mathrm{kg}$ group developed illness symptoms (hypoactivity, prostrate, salivation, lacrimation, yellow nose mucus secretion and poor appetite) on Day 20; anorexia and audible respiration were observed on Day 21; anorexia and poor appetite were observed on Day 22 and Day 23 to 24, respectively. A veterinarian's treatment was given to the animal dur-

Vol. 6 No. 3

Fig. 3. Effects of repeated oral dose of T. camphoratus extract on body weight in beagle dogs. Results of body weight in (A) male dogs and (B) female dogs treated with $T$. camphoratus extract for 28 days with additional 14 recovery days. No significant changes in body weight were observed in T. camphoratus extract treated animals. All data presented as mean $\pm$ S.D.
ing Day 20 to 24 and its health condition was improved on Day 22. According to the diagnosis results, the animal condition deteriorated markedly due to aspiration of vomit or idiopathic reason, resulted in interstitial lung disease. These findings were considered unrelated to the test article because of lack of dose dependency.

In ECG examination, the waveform morphology was evaluated by a veterinary cardiologist and the measured parameters including heart rate, RR interval, PR interval, QRS interval, QT interval and QT interval corrected for heart rate using Fridericia's formula were examined in all animals at pre-dose, end of treatment and recovery stages. The evaluated results showed no test article related
abnormalities in morphology and measured parameters. The only two statistical differences were found in female dogs: lower PR interval in $540 \mathrm{mg} / \mathrm{kg}$ group at pre-dose phase and higher PR interval in $900 \mathrm{mg} / \mathrm{kg}$ group at end of treatment (Table 11). These data was within the normal physiological range of dogs.

In clinical pathology evaluation (hematology, serum biochemistry and urine analysis), no significant toxicity effects were noted. Some statistical differences were observed when compared to vehicle control and described as follow. For hematology evaluation, higher activated partial thromboplastin time (APTT) in male rat of $540 \mathrm{mg} / \mathrm{kg}$ group at pre-dose phase was noted, but it was within normal physiological range (Table 12). For serum biochemistry evaluation, lower potassium in male rat of $900 \mathrm{mg} / \mathrm{kg}$ group at pre-dose phase, lower cholesterol in male rat of $1500 \mathrm{mg} / \mathrm{kg}$ group at end of treatment and higher triglyceride (TG) in male rat of $1500 \mathrm{mg} / \mathrm{kg}$ recovery group were noted. In addition, a minimal (about 2-fold) increase in ALT was observed in male rats of $1500 \mathrm{mg} / \mathrm{kg}$ group, but no other correlated parameters were affected and no pathologic findings were present from microscopic evaluation. This difference was not seen in recovery. Therefore, it was not considered to be of toxicological significance. In female rats, lower cholesterol in $1500 \mathrm{mg} / \mathrm{kg}$ group at end of treatment was noted. These values were within normal physiological range (Table 13).

There was no significant difference between control and each treatment groups in absolute and relative organ weight in main study animals (Table 14-15). Statistical lower spleen / body weight ratio in male ( $1500 \mathrm{mg} / \mathrm{kg}$ ) recovery group and higher kidney weight and lower adrenal / body weight ratio in female ( $1500 \mathrm{mg} / \mathrm{kg}$ ) recovery group were noted when compared to vehicle control (Table 14). All organ weight changes noted above were considered incidental and unrelated to treatment, due to individual variability and lack of microscopic correlations. The gross necropsy observation results showed that one male dog of $1500 \mathrm{mg} / \mathrm{kg}$ group had spontaneous unilateral absence of right epididymis (aplasia of right epididymis was confirmed by histopathological examination) (Table S15). In addition, the ill male dog of $425 \mathrm{mg} / \mathrm{kg}$ group developed illness symptoms on Day 20 showed diffuse yellow discoloration and diffuse firm abnormal consistency in lung at necropsy. Following histopathological examination, moderate diffuse interstitial mononuclear cell inflammation in lung was observed and it was considered unrelated to treatment. Moreover, there were no test article related histopathological changes in all animals at $1500 \mathrm{mg} / \mathrm{kg}$ (Table S16). This was the first study

## Toxicity studies of $T$. camphoratus extract

to explore the toxicity effect of T. camphoratus on beagle dogs. Based on the results, administration of T. camphoratus extract did not cause significant toxic effects in dogs at dose of $1500 \mathrm{mg} / \mathrm{kg}$. The results would provide more safety evidences for further medical use.

The results from in vitro and in vivo genotoxicity stud-
ies showed T. camphoratus extract had no mutagenic activity and genotoxicity. Besides, the results of repeated dose toxicity studies in rodent and non-rodent showed no significant toxicity evidences with the dosages up to $3400 \mathrm{mg} / \mathrm{kg}$ for male rats, $1700 \mathrm{mg} / \mathrm{kg}$ for female rats, and $1500 \mathrm{mg} / \mathrm{kg}$ for both genders of beagle dogs. Tak-

Table 11. Effect of T. camphoratus extract on ECG parameters in beagle dogs.

| Parameters | Gender | Dose (mg/kg) | Pre-dose | End of treatment | End of recovery |
| :---: | :---: | :---: | :---: | :---: | :---: |

[^3]en together, the present studies suggested T. camphoratus has highly safety properties for use in dietary supplements or medicinal products.

Conflict of interest---- The authors declare that there is no conflict of interest.
