(Received August 27, 2015; Accepted September 2, 2015)

ABSTRACT — Perfluoroalkyl carboxylic acids (PFCAs) are global environmental contaminants that are the cause of concern due to their possible effects on wildlife and human health. Since few studies have investigated the toxicity of long-chain PFCAs, we have performed combined repeated dose toxicity studies with the reproduction/developmental toxicity screening tests. We previously examined perfluoroundecanoic acid (C11), perfluorododecanoic acid (C12), and perfluorooctadecanoic acid (C18). We herein reported our results for perfluorotetradecanoic acid (PFTeDA; C14) and perfluorohexadecanoic acid (PFHxDA: C16). Male and female rats were administered PFTeDA at 1, 3 or 10 mg/kg/day or PFHxDA at 4, 20 or 100 mg/kg/day by gavage, and each female was then mated with a male in the same dose group after 14 days. Males were dosed for a total of 42 days and females were dosed throughout the gestation period until day 5 after parturition. PFTeDA and PFHxDA caused hepatocyte hypertrophy and/or fatty changes in the liver at the middle and high doses. PFTeDA also induced follicular cell hypertrophy in the thyroid at the middle and high doses. The only reproductive/developmental effect observed was an inhibited postnatal body weight gain in pups in the 10 mg/kg/day PFTeDA group. Based on these results, the NOAELs for the repeated dose and reproductive/developmental toxicity were concluded to be 1 and 3 mg/kg/day for PFTeDA and 4 and 100 mg/kg/day for PFHxDA, respectively. Our current and previous results indicate that the toxicity of PFCAs decreases with increases in the carbon chain length from 12 to 18.

Key words: Perfluoroalkyl carboxylic acids, Perfluorotetradecanoic acid, Perfluorohexadecanoic acid, Repeated dose toxicity, Reproductive and developmental toxicity, Rat

INTRODUCTION

A large number of chemicals are industrially produced and used without appropriate evaluations of their potential hazards to human health. The toxicity of these chemicals is continuously assessed in Japan by safety programmes for existing chemicals. These programmes have recently targeted perfluoroalkyl carboxylic acids (PFCAs) with carbon chain lengths of 11 to 18.

PFCAs are global environmental contaminants that are the cause of concern due to their possible effects on human health (Hekster *et al.*, 2003; Lau *et al.*, 2007; Post *et al.*, 2012). Although extensive toxicological research has been performed, especially on perfluorooctanoic acid (PFOA), which has a carbon chain length of 8, few studies have examined the toxicity of PFCAs with a carbon chain length of 11 and higher. Combined repeated dose toxicity studies with the reproduction/developmental toxicity screening tests (combined studies) have been conducted by Japanese safety programmes for existing chemicals in order to obtain initial toxicological information on such long-chain PFCAs.

We have reported our findings in combined studies on perfluoroundecanoic acid (PFUnA, C11), perfluorododecanoic acid (PFDoA, C12) and perfluorooctadecanoic acid (PFOcDA, C18) (Hirata-Koizumi *et al.*, 2012; Kato

Correspondence: Akihiko Hirose (E-mail: hirose@nihs.go.jp)

et al., in press; Takahashi *et al.*, 2014). We showed that the main toxic target of these long-chain PFCAs was the liver, but they also affected reproduction/development at the higher doses. Based on these findings, the NOAELs were concluded to be 0.1 mg/kg/day for PFUnA (C11) and PFDoA (C12) and 40 mg/kg/day for PFOcDA (C18). The value of NOAEL for repeated dose toxicity of PFOcDA (C18) was much higher than those of PFUnA (C11) and PFDoA (C12). The present study described the results obtained from combined studies on perfluorotetradecanoic acid (PFTeDA, C14, CAS No. 376-06-7) and perfluorohexadecanoic acid (PFHxDA, C16, CAS No. 67905-19-5), whose carbon lengths are in between previously reported substances. In this paper, we discuss the toxicity of PFCAs in terms of their carbon chain length.

MATERIALS AND METHODS

Combined repeated dose toxicity studies with the reproduction/developmental toxicity screening tests were performed on PFTeDA and PFHxDA at the Safety Research Institute for Chemical Compounds Co., Ltd. (Sapporo, Japan), according to the OECD guidelines for testing chemicals No. 422 under good laboratory practice (GLP) standards.

Chemicals and treatment

PFTeDA (lot No. 3728, purity: 96.5%) and PFHxDA (lot No. 1262, purity: 95.3%) were obtained from Exfluor Research Corporation (Round Rock, TX, USA). They were suspended in a 0.5% water solution of carboxymethylcellulose sodium, and administered by gavage. The homogeneity of test substances in the dosing solution and their stability until they were administered was confirmed before the start of the study. A separate control group was used for each chemical evaluation, and the control rats received vehicle only. The daily volume administered was 10 mL/kg, which was calculated based on the latest body weight. Dose levels were determined to be 1, 3, and 10 mg/kg/day or PFTeDA and 4, 20, and 100 mg/kg/day for PFHxDA based on the results of 14-day dose finding studies.

Animals and housing conditions

Eight-week-old male and female Crl:CD(SD) rats were purchased from Charles River Laboratories Japan, Inc. (Yokohama, Japan). This species and strain was selected because its reproductive performance is stable and sufficient historical data was available on this strain at the laboratory.

Following quarantine and acclimation periods, the animals were subjected to oral administration of PFTeDA or PFHxDA at 10 weeks of age. They were housed individually, except for the mating and lactation periods, in bracket-type metallic cages with a wire-mesh floor, and maintained in an air-conditioned room with controlled temperature (22 ± 3°C) and humidity (50 ± 20%). Light was provided on a 12-hr light/dark cycle (light: 8:00-20:00). All animals were fed *ad libitum* with a standard rat diet (CRF-1; Oriental Yeast Co., Ltd., Tokyo, Japan) and tap water. Pregnant females were reared using wood chips as bedding from day 17 of gestation to day 4 after delivery.

The present study protocols were approved by the Ethical Committee for animal experiments in the Safety Research Institute for Chemical Compounds Co., Ltd., and performed in accordance with the standard operational procedure contained in the Institutional Ethical Code for Animal Experiments. The use and care of animals complied with the Act on Welfare and Management of Animals (Japanese Animal Welfare Law, Act No. 105 of October 1, 1973. As amended up to Act No. 50 of June 2, 2006), Standards Relating to the Care, Management of Laboratory Animals and, Relief of Pain (Announcement No. 88 of Ministry of the Environment, Japan, dated April 28, 2006) and Guidelines for Animal Experimentation (Japanese Association for Laboratory Animal Science, dated May 22, 1987).

Study design

Male rats (12 animals/dose) were administered PFTeDA or PFHxDA for 14 days and then cohabited with females. This administration of PFTeDA or PFHxDA was continued during and after the mating period, and seven males in the control and high dose groups and all of animals in the low and middle dose groups were euthanized after a 42-day administration (main group). The remaining rats were maintained without the administration of PFTeDA or PFHxDA for 14 days after a 42-day administration and then euthanized for examination (recovery group).

Female rats were assigned to the main group or recovery group before PFTeDA and PFHxDA were administered. The number of females was 12 per dose in the main group, and PFTeDA or PFHxDA was administered for 14 days before mating, and continued throughout the mating, gestation, and lactation periods up to 5 days after parturition. In the recovery group, 5 females/dose (vehicle control and high dose only) were administered for 42 days without mating and euthanized after the 14-day recovery period.

Repeated dose toxicity evaluation

All animals were observed twice daily for general appearance and behavior. Detailed clinical observations, including evaluations in the home cage, during handling and outside the home cage in an open field, were also conducted using a standardized scoring system once a week. Body weight and food consumption was measured at regular intervals (at least once a week).

Males and females in the recovery group were subjected to urinalysis and functional observations in the sixth week of the administration period and second week of the recovery period. Functional observations were also performed for females in the main group on day 4 of lactation. The parameters examined were as follows:

- Functional observations: sensory reactivity to visual, tactile, auditory, pain, and proprioceptive stimuli, mid-air righting reflex, forelimb and hindlimb grip strength, and spontaneous motor activity
- Urinalysis: pH, protein, glucose, ketone body, urobilinogen, bilirubin, occult blood, color, urine volume, and specific gravity

The effects of the administration of PFTeDA and PFHxDA on hematology, blood biochemistry, organ weight, and histopathology were examined on the day after the final administration in the main group and after the completion of the recovery period in the recovery group. Serum thyroid-related hormone levels were also analyzed in the study on PFHxDA because changes were observed in thyroid weight.

The surviving rats were anesthetized deeply after 16- to 22-hr of starvation, and blood samples were collected from the abdominal aorta. The animals were then euthanized by exsanguination, and the organs and tissues of the entire body were examined macroscopically. The major organs were isolated and weighed, and organ weight per body weight (relative weight) was calculated. The eyeball and Harderian gland were fixed and preserved with Davidson's fixative solution. The testis and epididymis were fixed with Bouin's solution and preserved in 70% ethanol. The other organs were stored in 10% neutral-buffered formalin. All preserved organs in the control and high dose groups were sectioned, stained with hematoxylin-eosin, and examined under a light microscope. If treatment-related histopathological changes were found, the same tissues were examined in the low and middle dose groups. The parameters and organs examined were as follows:

- Hematology: red blood cell count, hematocrit, hemoglobin concentration, mean corpuscular volume, mean corpuscular hemoglobin, mean corpuscular hemoglobin concentration, reticulocyte count, platelet count, white blood cell count, differential count of white blood cells, prothrombin time (PT), and activated partial thromboplastin time (APTT)
- Blood biochemistry: total protein, albumin, albumin/globulin ratio, protein fraction ratio, glucose, total cholesterol, triglyceride, total bilirubin, urea nitrogen (BUN), creatinine, aspartate aminotransferase, alanine aminotransferase, alkaline phosphatase (ALP), γ-glutamyltranspeptidase, calcium, inorganic phosphorus (IP), sodium (Na), potassium, and chlorine (Cl)
- Hormonalysis (only in the study on PFHxDA): triiodothyronine (T_3), thyroxine (T_4), and thyroid-stimulating hormone (TSH)
- Organ weight: the brain, pituitary gland, thyroid, heart, liver, spleen, kidney, adrenal gland, thymus, testis, epididymis, prostate gland, seminal vesicle, and ovary
- Histopathology: the brain, spinal cord, pituitary gland, thymus, thyroid, adrenal gland, spleen, heart, esophagus, stomach, liver, pancreas, duodenum, jejunum, ileum, cecum, colon, rectum, trachea, lung, kidney, bladder, testis, epididymis, prostate, seminal vesicle, ovary, uterus, eyeball, Harderian gland, mammary gland, femur, mesenteric and mandibular lymph nodes, sciatic nerve, and grossly abnormal tissues

Reproductive/developmental toxicity evaluation

The estrous cyclicity was evaluated daily by vaginal lavage sampling from the first day of the administration period until evidence of copulation was detected in the main group and until the necropsy day in the recovery group. Females having repeated 4-6 day estrous cycles were judged to have normal estrous cycles.

During the mating period, males and females randomly selected from the same dose group were cohabited on a 1:1 basis until successful copulation occurred for a maximum of 14 days. The presence of sperm in the vaginal smear and/or a vaginal plug was considered to be evidence of successful mating. The day of successful mating was designated as day 0 of gestation. Successfully cohabited females were allowed to spontaneously deliver and nurse their pups until the end of the study. They were checked at least three times daily on days 21-25 of gestation, and the day on which dams held their pups under the abdomen in the nest by 9:00 was designated as day 0 of lactation or postnatal day (PND) 0. Gestational length was recorded, and the following indices were computed for each dose group.

$$\text{Copulation index (\%)} = \frac{\text{Number of animals with successful copulation}}{\text{Number of animals cohabited}} \times 100$$

$$\text{Fertility index (\%)} = \frac{\text{Number of pregnant females}}{\text{Number of pairs with successful copulation}} \times 100$$

$$\text{Gestation index (\%)} = \frac{\text{Number of females with live pups}}{\text{Number of pregnant females}} \times 100$$

All live and dead pups born were counted, and live pups were sexed and examined grossly on PND 0. They were observed daily for general appearance and behavior, and the body weight of live pups was recorded on PNDs 0, 1, and 4. On PND 4, the pups were euthanized and subjected to a gross external and internal observation. At necropsy of maternal animals, the numbers of corpora lutea in the ovary and implantation sites in the uterus were recorded.

Statistical analysis

Parametric data were evaluated by Bartlett's test for the homogeneity of variances. The neonatal sex ratio and body weights of male and female pups were analyzed using the litter as the experimental unit. When homogeneity was recognized, a one-way analysis of variance was applied. If a significant difference was found, Dunnett's test was used for pairwise comparisons between the control and individual treatment groups. Data without homogeneity were subjected to the Kruskal-Wallis test, and if significant differences were detected, the Mann-Whitney U test was used to compare PFTeDA- or PFHxDA-treated groups with the correspondent control group.

The results of the detailed clinical and functional observations, qualitative parameters of urinalysis, specific gravity of urine, and histopathological findings with multiple grades were evaluated for the trend in each group by the Kruskal-Wallis test. When significant differences were found, data were compared between the control and each dosage group using the Mann-Whitney U test. The incidence of females with normal estrous cycles, copulation, fertility, and gestation indices, and histopathological findings with a single grade were analyzed using the chi-square test or Fisher's exact test.

RESULTS

Perfluorotetradecanoic acid (PFTeDA; C14)

Repeated dose toxicity

No treatment-related abnormalities were observed in general appearance or behavior throughout the administration and recovery periods. In the 10 mg/kg/day group, the body weights of male rats were significantly lower than those in the control group on days 7 and 14 of the recovery period (Fig. 1). Although similar results were observed in the female recovery group, significant differences were not observed from the control. Body weights in the female main group were significantly lower on day 4 of the lactation period at 3 mg/kg/day and during the lactation period at 10 mg/kg/day. A significant decrease in food consumption was only found in females given

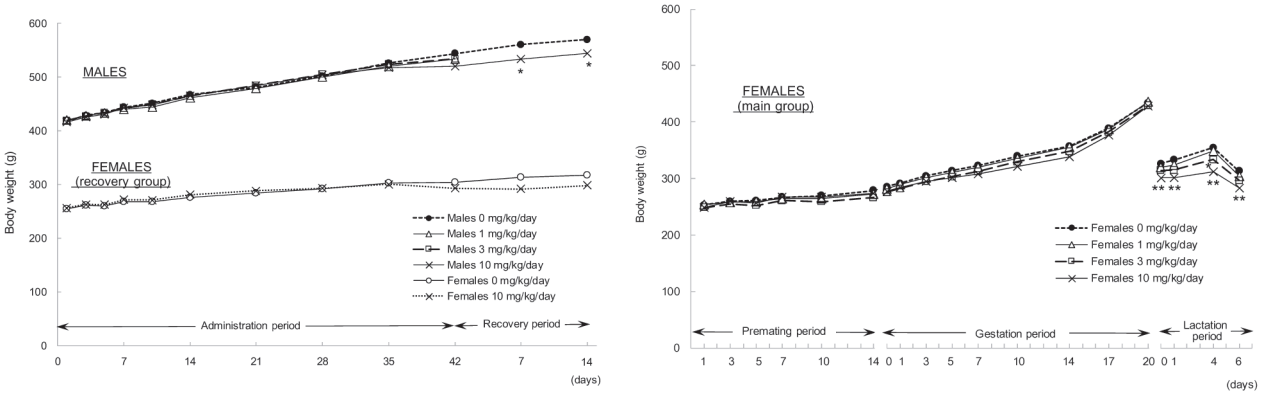

Fig. 1. Body weight changes in the combined repeated dose toxicity study with the reproduction/developmental toxicity screening test for PFTeDA in rats. *: Significantly different from the control, $P \leq 0.05$. **: Significantly different from the control, $P \leq 0.01$.

10 mg PFTeDA/kg/day in the main group on days 5 and 10 of gestation and on day 4 of lactation (data not shown).

At the end of the administration period, the hindlimb grip strength of male rats decreased in a dose-dependent manner, and a significant difference from the control was found in the 3 and 10 mg/kg/day groups (Fig. 2). No significant changes were observed in grip strength in males of the recovery group or in females. Furthermore, no significant differences were observed in urinalysis parameters between the PFTeDA-treated and control groups, either at the end of the administration period or at the end of the recovery period (data not shown).

In the main group, the only significant effect observed on hematology was a shortening in APTT in males given 10 mg PFTeDA/kg/day (Table 1). Blood biochemical examinations showed significant decreases in total protein in males and the β-globulin fraction in both sexes at 10 mg/kg/day (Table 1). Significant increases were also observed in ALP and BUN in males and Cl in females in the 10 mg/kg/day group. Absolute and relative liver weights were significantly increased at 3 and 10 mg/kg/day in males (Table 1). A significant increase in the relative liver weight was also found in females at 10 mg/kg/day. In males, the absolute weight of the pituitary gland was significantly decreased at 3 and 10 mg/kg/day and the relative weight was also significantly decreased at 3 mg/kg/day. The absolute weight of the seminal vesicle was significantly decreased at all doses.

Histopathologically, centrilobular hepatocyte hypertrophy was observed in males at 3 and 10 mg/kg/day and in females at 10 mg/kg/day (Table 2). Microgranulomas were noted in the liver of both sexes in all groups containing the control; however, the extent of these was significantly higher in females given 10 mg PFTeDA/kg/day. Focal necrosis was detected in the liver of one female given 10 mg PFTeDA/kg/day. Follicular cell hypertrophy was observed in the thyroids of males at 3 and 10 mg/kg/day. In females, the incidences of decreases in extramedullary hematopoiesis in the spleen and cortex atrophy in the thymus were significantly increased at 10 mg/kg/day. No treatment-related changes were detected in histopathology in other organs, including the pituitary gland and seminal vesicle.

In the recovery group, the hemoglobin concentration and hematocrit value were significantly decreased, and PT was significantly shortened in females in the 10 mg/kg/day group (Table 1). Significant increases were also observed in ALP and IP and decreases in triglyceride levels in males, as well as a significant decrease in total cholesterol and increase in BUN in females in the 10 mg/kg/day group. In this group, the absolute and/or relative liver weights were significantly increased, and histopathologically, centrilobular hypertrophy of hepatocytes, diffuse hypertrophy of hepatocytes or diffuse fatty change was found in the liver (Table 2). Hypertrophy of follicular cells was observed in the thyroids of two males in the 10 mg/kg/day group.

Reproductive/developmental toxicity

Reproductive/developmental results are summarized in Table 3. No significant changes were found in reproduc-

Values represent the number of animals with findings.
+: Slight change, ++: moderate change
*: Significantly different from the control group at $P \leq 0.05$.
**: Significantly different from the control group at $P \leq 0.01$.
Brackets in the data columns mean that statistical analysis was performed for a total number of animals with findings in consideration of grades.

tive parameters, including estrous cyclicity, the copulation index, fertility index, gestation index or gestation length. No significant differences were observed in the number of corpora lutea, implantation sites, delivered pups, or live pups on PNDs 0 and 4, or in the sex ratio of live pups between the PFTeDA-treated and control groups. In the 10 mg/kg/day group, the body weights of male and female pups were significantly lower on PNDs 1 and 4. There were no abnormalities in the general appearance or necropsy findings of neonates.

Perfluorohexadecanoic acid (PFHxDA: C16)

Repeated dose toxicity

No treatment-related clinical signs of toxicity were observed throughout the study. The body weights of males in the 100 mg/kg/day group were significantly lower than those of the control on days 35 and 42 of the administration period (Fig. 3). Such effects on body weight were not detected in the females. Food consumption was significantly reduced on day 14 of the recovery period in males given 100 mg PFHxDA/kg/day, on days 5-14 of the gestation period, and on day 4 of the lactation period in females given 100 mg PFHxDA/kg/day in the main group (data not shown).

A functional observation at the end of the administration period revealed no significant changes in any of the PFHxDA-treated groups, but a significant decrease in hindlimb grip strength at the end of recovery period in both sexes given 100 mg PFHxDA/kg/day (Fig. 4). No significant difference was seen in any urinalysis parameters between the control and PFHxDA-treated groups either at the end of the administration period or at the end of the recovery period (data not shown).

At the end of the administration period, no significant differences were observed in any hematological parameters between the control and PFHxDA-treated groups

(data not shown). Serum Cl levels were significantly increased at 100 mg/kg/day in males and at 20 and 100 mg/kg/day in females (Table 4). A significant decrease in serum total bilirubin levels and significant increases in BUN and serum Na levels were also detected in females given 100 mg PFHxDA/kg/day. In males, the absolute and relative liver weights were significantly increased in the 100 mg/kg/day group (Table 4). The relative thyroid weight was significantly increased at 20 and 100 mg/kg/day, with a significant increase also being observed in the absolute weight at 20 mg/kg/day in males. The analysis of serum thyroid-related hormones revealed significantly decreased T_3 in females in all PFHxDA-treated groups. The histopathological examination revealed the centrilobular hypertrophy of hepatocytes in males at 20 mg/kg/day and in both sexes at 100 mg/kg/day (Table 5). Centrilobular fatty changes were also observed in males at 20 and 100 mg/kg/day. No treatment-related histopathological changes were detected in other organs including the thyroid.

A significant decrease was noted in serum total bilirubin levels in both sexes as well as a significant increase in serum Cl level in females in the 100 mg/kg/day group after the 14-day recovery period (Table 4). Serum T_4 levels were significantly decreased in males in the 100 mg/kg/day group. Absolute and relative liver weights in males still remained higher, and in addition, significant decreases were found in absolute and relative adrenal weights in the 100 mg/kg/day group. Histopathologically, the centrilobular hypertrophy of hepatocytes was observed in both sexes as well as centrilobular fatty changes in one male in the 100 mg/kg/day group (Table 5).

Reproductive/developmental toxicity

PFHxDA did not significantly affect any reproductive/developmental parameters (Table 6). Although the body weights of male and female pups on PND 4 were slightly lower in the 100 mg/kg/day group, no significant difference was observed from those in the control group. There were no abnormalities in the general appearance or necropsy findings of neonates.

DISCUSSION

The present study was performed to obtain initial information on the repeated dose and reproductive/developmental toxicity of PFTeDA (C14) and PFHxDA (C16). The results obtained demonstrated that the main toxic target of these compounds was the liver, which was similar to PFUnA (C11), PFDoA (C12), and PFOcDA (C18), which we had examined previously (Hirata-Koizumi *et al.*, 2012; Kato *et al.*, in press; Takahashi *et al.*, 2014).

The hepatic effects of PFCAs in rodents have been attributed, at least partly, to the peroxisome proliferator-activated receptor alpha (PPARα) (Lau *et al.*, 2007; Wolf *et al.*, 2012). PPARα is a nuclear receptor that plays an important role in regulating fatty acid metabolism in tissues such as the liver, kidney, heart, and intestinal mucosa (Corton *et al.*, 2000). In the present study, the blood biochemical examination did not reveal any clear effects on lipid metabolism; however, PFTeDA (C14) and PFHxDA (C16) decreased serum total cholesterol in the 14-day dose finding study performed at higher doses. Although the PPARα agonist activities of PFTeDA and PFHxDA are unknown, PFDoA (C12), which is very similar in

structure, was recently reported to activate mouse PPARα in transiently transfected COS-1 cells (Wolf *et al.*, 2012) and induce the mRNA levels of the important PPARα target genes, acyl CoA oxidase and CYP4A1, in the rat liver (Zhang *et al.*, 2008; Ding *et al.*, 2009). These findings indicated that PFTeDA and PFHxDA may activate PPARα, which may in turn affect the liver. Regarding the mechanism underlying the hepatotoxicity of PFCAs, many studies have examined PFOA (C8) and showed that PFOA could elicit changes in the liver not only via PPARα activation, but also through PPARα-independent mechanisms (Peters and Gonzalez, 2011). The involvement of other transcription factors such as the constitutive androstane receptor and pregnane X receptor has been implied. Further research is needed to clarify the mechanism involved in the hepatotoxicity of PFCAs including PFTeDA and PFHxDA.

PFTeDA (C14) induced follicular cell hypertrophy in

Table 7. Comparison of the NOAELs for the repeated dose and reproductive/developmental toxicity for long-chain PFCAs.

Chemical name	Carbon number	NOAEL (mg/kg/day)		Reference
		Repeated dose toxicity	Reproductive /developmental toxicity	
PFUnA (perfluoroundacanoic acid)	11	0.1	0.3	Takahashi *et al.*, 2014
PFDoA (perfluorododecanoic acid)	12	0.1	0.5	Kato *et al.*, in press
PFTeDA (perfluorotetradecanoic acid)	14	1	3	Current study
PFHxDA (perfluorohexadecanoic acid)	16	4	100	Current study
PFOcDA (perfluorooctadecanoic acid)	18	40	200	Hirata-Koizumi *et al.*, 2012

The NOAELs were established based on the results of in the combined repeated dose toxicity study with reproduction/developmental toxicity screening tests in rats

the thyroids of males. Although the serum levels of thyroid-related hormones were not analyzed in the present study for PFTeDA, it may be a compensatory response of the thyroid to a decrease in thyroid hormone levels because the structural analogue, perfluorodecanoic acid (PFDeA, C10), was previously reported to reduce serum T_3 and/or T_4 levels in rats (Gutshall *et al.*, 1988; Van Rafelghem *et al.*, 1987; Langley and Pilcher, 1985; Gutshall *et al.*, 1989). In the present study, PFHxDA (C16) did not affect the histopathology of thyroids, but increased the thyroid weight in males and decreased serum T_3 level in females. Although these effects of PFHxDA were not consistent between sexes and lacked clear dose-dependency, our results indicate that PFHxDA may slightly affect the thyroid system through a similar mechanism to PFTeDA (C14) and PFDeA (C10). The findings of mechanistic studies on PFDeA (C10) suggested that reduced serum thyroid hormone levels may result from (1) a displacement in the hormones from plasma protein binding sites, leading to an increase in tissue uptake and turnover (Gutshall *et al.*, 1989), and (2) the enhanced metabolism of thyroid hormones in the liver (Shelby and Klaassen, 2006). In our previous studies, we did not detect any effects of PFUnA (C11), PFDoA (C12), and PFOcDA (C18) on the histopathology or weight of the thyroids (Hirata-Koizumi *et al.*, 2012; Kato *et al.*, in press; Takahashi *et al.*, 2014). Serum hormone levels were not measured in these studies.

We previously reported that PFOcDA (C18) reduced forelimb grip strength in females (Hirata-Koizumi *et al.*, 2012). This effect was not observed at the end of the administration period, but appeared at the end of recovery period in both sexes in studies on PFUnA (C11) and PFDoA (C12) (Kato *et al.*, in press; Takahashi *et al.*, 2014). We considered that the reduction observed in grip strength may reflect the muscle weakness associated with a decrease in food consumption and/or body weight. In the present study, PFTeDA (C14) and PFHxDA (C16) reduced hindlimb grip strength, but not that of the forelimb. As with PFUnA (C11) and PFDoA (C12), the effects of PFHxDA (C16) on grip strength only appeared at the end of the recovery period. Hindlimb grip weakness was not necessarily accompanied by a low body weight. Further studies are required in order to clarify the mechanism responsible.

As for reproductive/developmental toxicity, the only effect observed was an inhibited postnatal body weight gain in pups at a maternal toxic dose of PFTeDA (C14). Similar results were observed in the study on PFHxDA (C16), but these changes were not significant. In our previous studies on long-chain PFCAs, postnatal body weight gain in pups was also inhibited at the highest dose (Hirata-Koizumi *et al.*, 2012; Kato *et al.*, in press; Takahashi *et al.*, 2014). In studies performed on PFDoA (C12) and PFOcDA (C18), such effects were accompanied by more severe reproductive/developmental effects, such as the deaths of dams at the end of pregnancy and stillbirths, and with more severe maternal toxic effects than those observed in the present study. The effect of long-chain PFCAs on postnatal development could be attributed to secondary effects due to maternal toxicity such as a low body weight during the lactation period. If PFTeDA (C14) reduced thyroid hormone levels as speculated above, it may be one cause of impaired postnatal development because Hapon *et al.* (2003) reported that hypothyroidism induced by a propylthiouracyl treatment impaired the growth of pups during the lactation period in rats. When the lipophilic properties of long-chain PFCAs (Inoue *et al.*, 2012) are considered, there is also the possibility that they were transferred via breast milk and affected the pups directly.

Based on the present results, the NOAELs for the repeated dose and reproductive/developmental toxicity were concluded to be 1 and 3 mg/kg/day for PFTe-

DA (C14) and 4 and 100 mg/kg/day for PFHxDA (C16), respectively. When the NOAELs were compared with those of PFUnA (C11), PFDoA (C12), and PFOcDA (C18) from our previous studies, the toxic potency of PFCAs was found to become weaker as the carbon chain length increased from C12 to C18 (Table 7). Since the previous comparative studies on the hepatic effects of PFCAs demonstrated increases in toxic potency due to an increase in the length of carbon chains up to C8 in rodents (Kudo *et al.*, 2006; Permadi *et al.*, 1993), the toxic potency of PFCAs was considered to be the strongest when the carbon length was C8 to C12. A clear chain length-dependent downward trend was observed in the renal elimination of PFCAs with a carbon chain length from C6 to C10 in rats (Ohmori *et al.*, 2003; Kudo *et al.*, 2001), and active renal tubular reabsorption via organic anion transport proteins was considered to be responsible for this (Han *et al.*, 2012). On the other hand, Wolf *et al*. (2008, 2012) reported that PFCAs of longer chain lengths induced more activity from mouse and human PPARα than those of shorter chain lengths up to C9 in transiently transfected COS-1 cells; therefore, not only toxicokinetic, but also toxicodynamic factors may contribute to the chain length-dependent toxicity of PFCAs with carbon chain lengths up to C8. Regarding PFCAs with carbon chain lengths of C11 and above, although no data is currently available to explain the cause of the chain length-dependent differences in toxic potencies, medium chain fatty acids (typically C6-C12) are known to be absorbed better from the gastrointestinal tract than long-chain fatty acids (typically longer than C12) (Ramirez *et al.*, 2001). Considering structural similarities, the gastrointestinal absorption of longer chain PFCAs may be poorer than that of PFCAs with shorter carbon chains. In order to clarify the cause of the differences in the toxic potencies of long-chain PFCAs, we are planning to first analyze serum PFCA levels in rats given different long-chain PFCAs.

ACKNOWLEDGMENTS

This study was undertaken under the safety programmes for existing chemicals funded by the Ministry of Health, Labour and Welfare, Japan, and supported by a Health and Labour Sciences Research Grant (H25-Kenki-Ippan-007) from the Ministry of Health, Labour and Welfare, Japan.

Conflict of interest---- The authors declare that there is no conflict of interest.
